Λ	1. (Currently amended) A method for using empirical measurements of
acke	esses to synchronization points within an application to construct a
perf	ormance model for the application, comprising:

modifying the application to record statistics related to the synchronization points within the application;

running the application to produce the statistics related to synchronization points;

constructing the performance model based upon the statistics. wherein the performance model is a queuing system model in which synchronization points in the application are represented by service centers in the queuing system model;

11 and

using the performance model to predict a performance of the application.

2. (Original) The method of claim 1,

wherein constructing the performance model based upon the statistics involves constructing an analytic model for the application; and

wherein using the performance model to predict the performance involves numerically solving the analytic model to predict the performance for the

6 application.

3. (Original) The method of claim 1,

	· ·
2	wherein constructing the performance model based upon the statistics
3	involves constructing a simulation model for the application; and
4	wherein using the performance model to predict the performance involves
5	running the simulation model to predict the performance for the application.
1	4. (Original) The method of claim 1, wherein modifying the application
2	involves compiling the application with a profiling option in order to record the
3	statistics related to the synchronization points.
1	5. (Original) The method of claim 1, wherein modifying the application
2	involves modifying the executable code of the application to record the statistics
3	during system calls that operate on the synchronization points.
1	6. (Original) The method of claim 1, wherein the statistics include:
2	an identifier for a calling function;
3	an identifier for a mutual exclusion variable;
4	a time spent holding the mutual exclusion variable; and
5	a frequency of accesses to the mutual exclusion variable.
1	7. (Original) The method of claim 1 wherein the statistics include a
2	directed call graph specifying an ordering of function calls.
1	8. (Original) The method of claim 7, wherein constructing the performance
2	model involves constructing a queuing model, wherein each synchronization poin
3	is a service center for jobs representing processes that circulate between service
4	centers in a manner specified by the directed call graph.

9. (Currently amended) A computer-readable storage medium storing
instructions that when executed by a computer cause the computer to perform a
method for using empirical measurements of accesses to synchronization points
within an application to construct a performance model for the application, the
method comprising:
modifying the application to record statistics related to the synchronization
points within the application;
running the application to produce the statistics related to synchronization
points;
constructing the performance model based upon the statistics, wherein the
performance model is a queuing system model in which synchronization points in
the application are represented by service centers in the queuing system model;
and
using the performance model to predict a performance of the application.
10. (Original) The computer-readable storage medium of claim 9,
wherein constructing the performance model based upon the statistics
involves constructing an analytic model for the application; and
wherein using the performance model to predict the performance involves
numerically solving the analytic model to predict the performance for the
application.
11. (Original) The computer-readable storage medium of claim 9,
wherein constructing the performance model based upon the statistics
involves constructing a simulation model for the application; and
wherein using the performance model to predict the performance involves
running the simulation model to predict the performance for the application.

	I.
1	12. (Original) The computer-readable storage medium of claim 9, wherein
2	modifying the application involves compiling the application with a profiling
3	option in order to record the statistics related to the synchronization points.
1	13. (Original) The computer-readable storage medium of claim 9, wherein
2	modifying the application involves modifying the executable code of the
3	application to record the statistics during system calls that operate on the
4	synchronization points.
1	14. (Original) The computer-readable storage medium of claim 9, wherein
2	the statistics include:
3	an identifier for a calling function;
4	an identifier for a mutual exclusion variable;
5	a time spent holding the mutual exclusion variable; and
6	a frequency of accesses to the mutual exclusion variable.
1	15. (Original) The computer-readable storage medium of claim 9, wherein
2	the statistics include a directed call graph specifying an ordering of function calls.
1	16. (Original) The computer-readable storage medium of claim 15,
2	wherein constructing the performance model involves constructing a queuing
3	model, wherein each synchronization point is a service center for jobs
4	representing processes that circulate between service centers in a manner specified
5	by the directed call graph.
1	17. (Currently amended) An apparatus for using empirical measurements
2	of accesses to synchronization points within an application to construct a
3	performance model for the application, comprising:
	_{5}

4	a modification mechanism that is configured to modify the application to
5	record statistics related to the synchronization points within the application;
6	an execution mechanism that is configured to run the application to
7	produce the statistics related to synchronization points;
8	a performance model construction mechanism that is configured to
9	construct the performance model based upon the statistics, wherein the
10	performance model is a queuing system model in which synchronization points in
11	the application are represented by service centers in the queuing system model;
12	and
13	a performance predicting mechanism that is configured to use the
14	performance model to predict a performance of the application.
1	18. (Original) The apparatus of claim 17,
2	wherein the performance model construction mechanism is configured to
3	construct an analytic model for the application; and
4	wherein the performance predicting mechanism is configured to predict
5	the performance of the application by numerically solving the analytic model.
1	19. (Original) The apparatus of claim 17,
2	wherein the performance model construction mechanism is configured to
3	construct a simulation model for the application; and
4	wherein the performance predicting mechanism is configured to predict
5	the performance of the application by running the simulation model.
1	20. (Original) The apparatus of claim 17, wherein the modification
2	mechanism is configured to compile the application with a profiling option in
3	order to record the statistics related to the synchronization points.

1	21. (Original) The apparatus of claim 17, wherein the modification
2	mechanism is configured to modify the executable code of the application to
3	record the statistics during system dalls that operate on the synchronization points.
1	22. (Original) The apparatus of claim 17, wherein the statistics include:
2	an identifier for a calling function;
3	an identifier for a mutual exclusion variable;
4	a time spent holding the mutual exclusion variable; and
5	a frequency of accesses to the mutual exclusion variable.
1	23. (Original) The apparatus of claim 17, wherein the statistics include a
2	directed call graph specifying an ordering of function calls.
1	24. (Original) The apparatus of claim 23, wherein the performance model
2	construction mechanism is configured to construct a queuing model, wherein each
3	synchronization point is a service center for jobs representing processes that
4	circulate between service centers in a manner specified by the directed call graph.
